

# How to Install and Setup WordPress Multisite Network

Do you want to set up and install WordPress multisite network? WordPress comes with a built-in capability to create multiple websites using the same WordPress installation.

A WordPress multisite network is used by blogs, schools, and businesses, who need to run separate websites but want to manage them under one dashboard.

In this article, we will show you how to properly install and setup a WordPress multisite network.

Since this is a comprehensive article, we have added the table of contents for easier navigation:

## **What is WordPress Multisite Network?**

A WordPress [Multisite](#) network allows you to run and manage multiple WordPress sites or blogs from a single WordPress installation.

It enables you to create new sites instantly and manage them using the same username and password. You can even allow other users to signup and create their own blogs on your domain.

The WordPress multisite network comes with advanced settings that you can use to customize each website / blog on your network.

## **Pros of Using a WordPress Multisite Network**

In many situations, a WordPress multisite network can be more useful than managing multiple standalone WordPress sites. Here are some of the advantages of using a WordPress multisite network:

1. As the network administrator, you can easily manage multiple sites from a single dashboard.
2. Each site on the network can have its own admins. The site admins will have the capabilities to manage only their own website.

3. You can install plugins / themes and activate them for multiple sites with one download.
4. Multisite network also makes it easier for you to manage updates. You only need to update your WordPress, plugins, or themes on one “master” install.

## Cons of Using a WordPress Multisite Network

Creating a WordPress multisite network is not always helpful in managing multiple sites. Here are some of the disadvantages that you should keep in mind before setting up a multisite network.

1. All sites on the network share the same resources. This means that when your network is down, all other sites go down as well.
2. It's not easy to manage traffic and server resources for the beginner level users. In case, one of your websites gets unexpected traffic, then it will affect all other websites on the network.
3. If one website gets hacked, then this means all sites on your network will get hacked.
4. Some WordPress plugins may not work well on a multisite network.
5. WordPress multisite network is not properly supported by all web hosting providers which limits your options. We will talk more about this later in the article.

## Who needs a WordPress multisite network?

Just because you manage multiple WordPress websites does not mean you need to start using a multisite network.

There are third party [tools to manage multiple WordPress sites](#) from a single dashboard. Tools like [InfiniteWP](#) or [iThemes Sync](#) make it easier to maintain multiple WordPress sites under one roof without switching back and forth from one site to another.

Here are some scenarios when creating a multisite network makes sense:

1. A magazine website with different sections managed by different teams.
2. A [business website](#) with sub-sites for different locations and branches.
3. Government or non-profit websites can use WordPress multisite for different departments, locations, and regions.
4. Your own network of blogs running on multiple subdomains.
5. Schools and colleges allowing students to create their own blogs on school servers.

## Requirements for a WordPress Multisite Network

All websites on a WordPress multisite network share the same server resources. This means that the most important thing you will need is a [good WordPress hosting](#).

If you are planning on having just a couple of websites with low traffic, then you can probably get away with [shared hosting](#).

However, due to the nature of multisite network, you'd need [VPS hosting](#) or a dedicated server as your sites grow.

We recommend [Bluehost](#) because they offer both shared hosting and VPS/Dedicated servers, and they are also one of the official WordPress hosting partners.

If you're looking for an alternative, then [SiteGround](#) and [WP Engine](#) provide excellent service for WordPress multisite network.

Apart from web hosting, you will need the basic knowledge of [how to install WordPress](#) and [editing files using FTP](#).

## Choosing a Domain Structure for your Multisite Network

On a WordPress multisite network, you can add new sites using either [subdomains](#) or sub-directories.

### **Example of subdomain:**

`http://site1.example.com`

### **Example of sub-directory:**

`http://example.com/site1/`

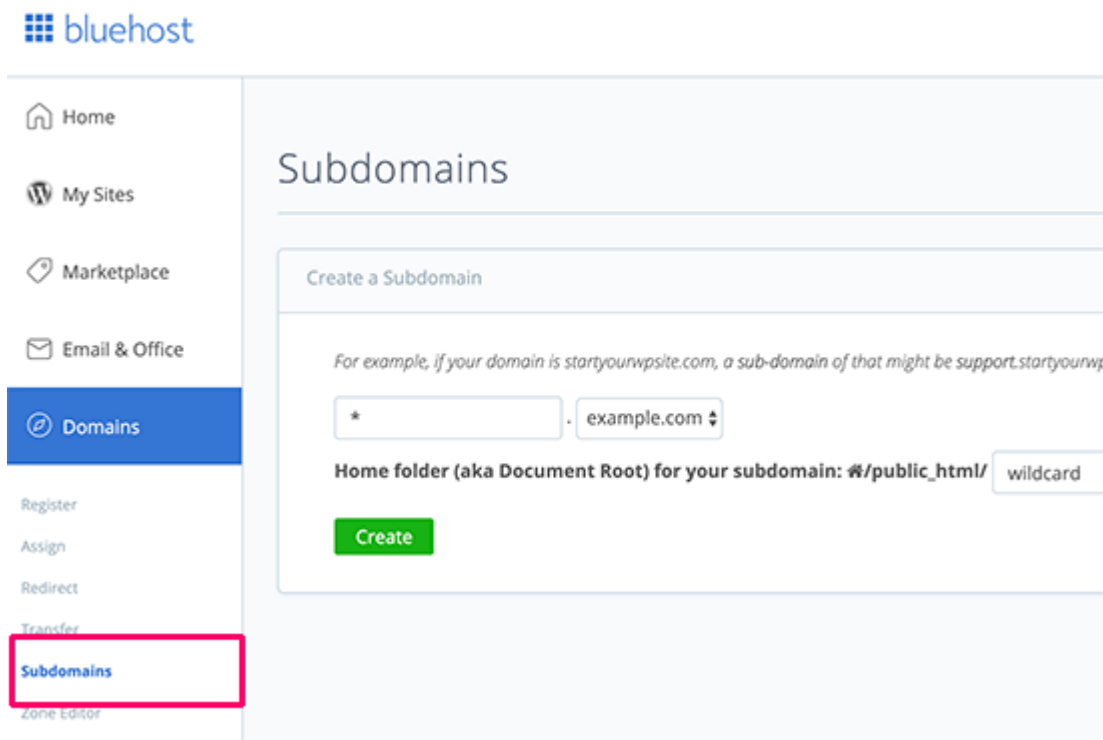

If you choose subdomains, then you will have to configure wildcard subdomains on your server. We will show you how to do that in the next step.

On the other hand, if you choose sub-directories or path based URLs for sites on your network, then you can skip the next step.

## Setting Up Wildcard Subdomains

If you decide to use subdomains for websites on your multisite network, then you will need to setup wildcard subdomains for your multisite network.

To do that, first you need to login to your WordPress hosting account's [cPanel](#) dashboard. After that, you need to scroll down to the 'Domains' section and then click on 'Subdomains'.

**Note:** Depending on your web hosting service, your cPanel dashboard may look slightly different than the screenshot above. This screenshot is from the cPanel on [Bluehost](#).

On the next page, you need to enter the \* sign in the subdomain field and select your main domain from the drop-down menu.

## Subdomains

Subdomains are URLs for different sections of your website, which have an added *prefix* relative to your accounts home directory. The 🏠 icon signifies your home directory.

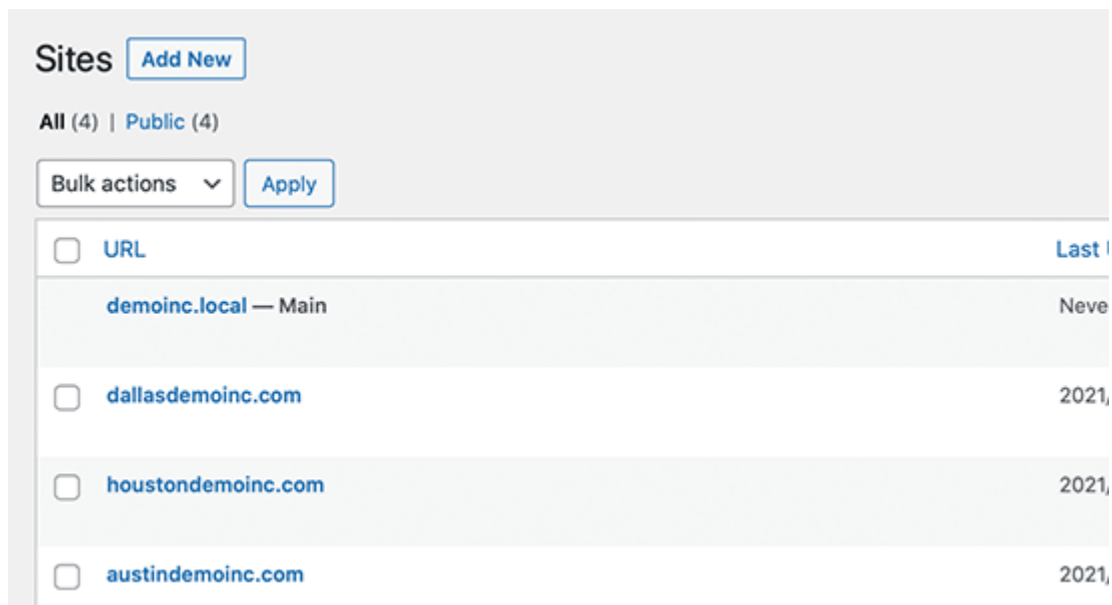

The image shows a 'create a subdomain' form. At the top is a blue header bar with the text 'create a subdomain'. Below the header is an example text: 'For example, if your domain is blewhost.com, a **sub-domain** of that might be **support**'. The form has two input fields: a text field containing an asterisk (\*) and a dropdown menu showing 'example.com'. Below these fields, it says 'Home folder (aka Document Root) for your subdomain: 🏠/public\_html/' with a 'wildcard' button to its right. At the bottom of the form is a green 'create' button.

Cpanel will automatically detect the document root and will display it in the field below. Now click on the 'Create' button to add your wildcard subdomain.

## Setting up Custom Domains for Each Site

WordPress multisite also allows you to set different domains for each website in your multisite network.

To set up custom domains, you'll need to use the domain mapping feature and update nameserver records in your [domain registrar](#) account.

We have created a detailed step by step guide on [how to create WordPress multisite with different domains](#) for the setup instructions.

## Enabling WordPress Multisite Network Feature

Multisite Network feature comes built-in with each WordPress installation. All you need to do is [install and setup WordPress](#) like you normally would. After that, you just need to enable the multisite feature.

You can also enable the multisite feature on any existing WordPress site. Before you enable multisite, don't forget to create a [complete backup of your WordPress site](#).

To enable Multisite, connect to your site using a [FTP client](#) or cPanel file manager, and open the [wp-config.php file](#) for editing.

You need to add the following code to your wp-config.php file just before the `/* That's all, stop editing! Happy blogging. */` line.

```
1/* Multisite */
2define( 'WP_ALLOW_MULTISITE', true );
```

Once you are done, you can save and upload your wp-config.php file back to the server.

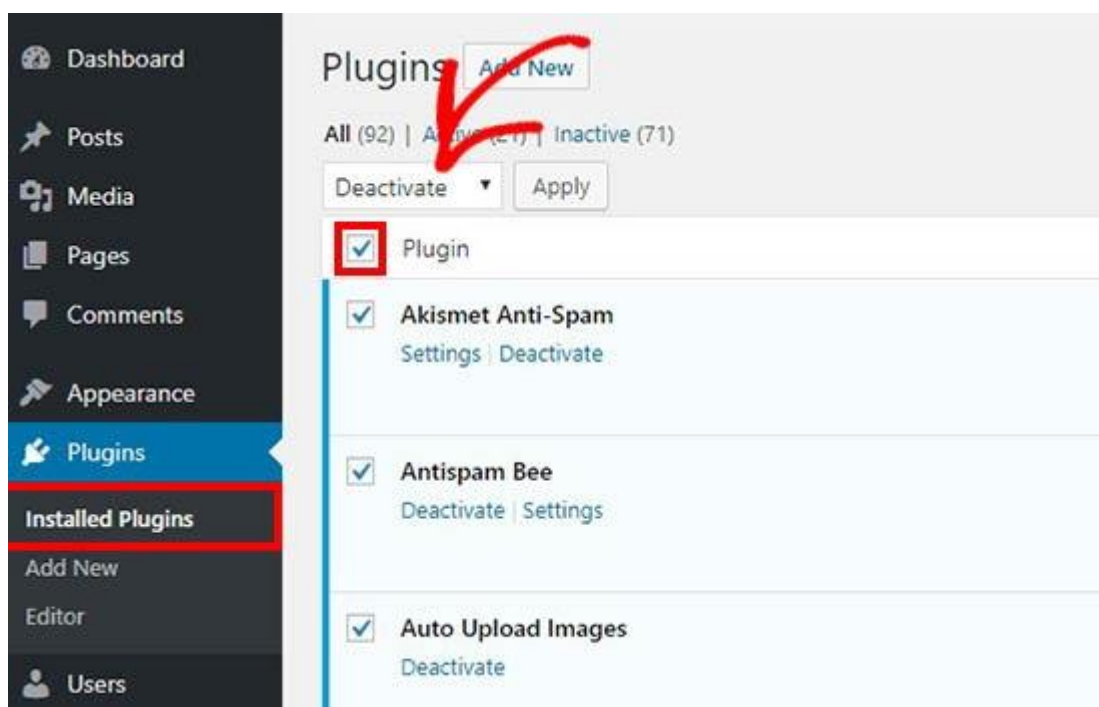

This code simply enables the multisite feature on your WordPress site. Once enabled, you will still need to setup the multisite network.

## Setting Up Your WordPress Multisite Network

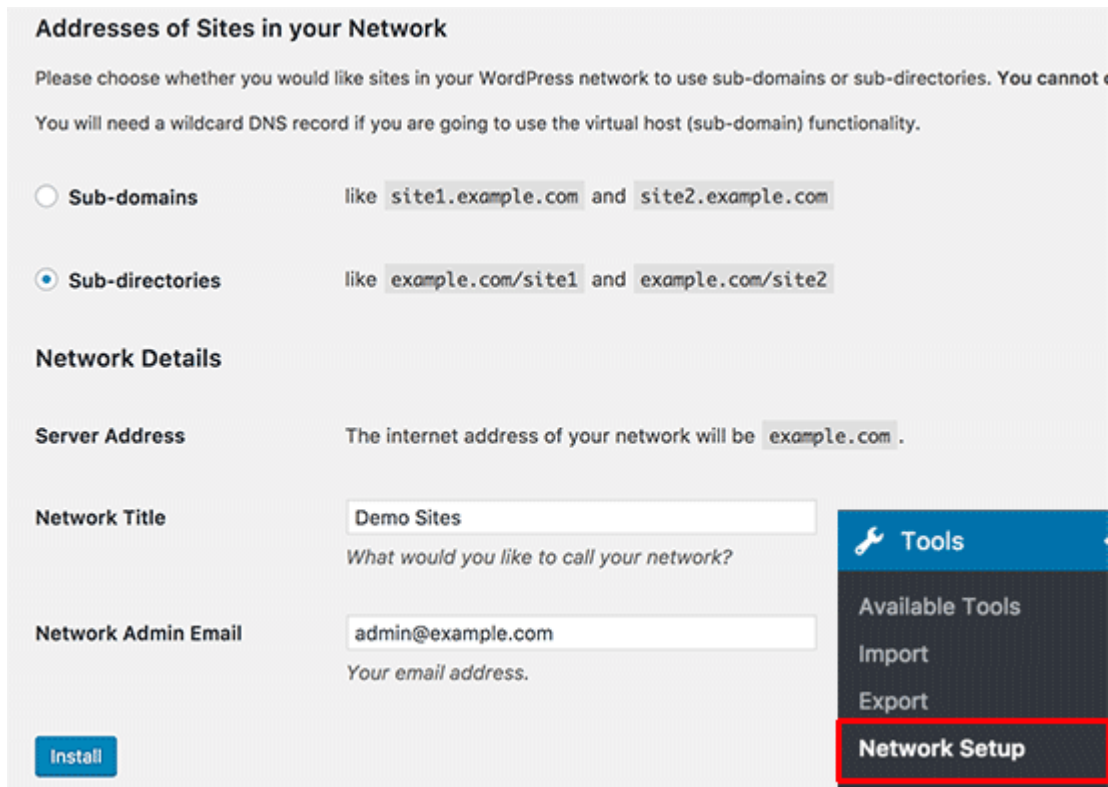

Now that you have successfully enabled the Multisite Network feature on your WordPress site, it is time to set up your network.

If you are setting up a multisite network on an existing WordPress website, then you will need to deactivate all plugins on your site.

Simply visit the **Plugins » Installed Plugins** page and select all plugins. You need to select 'Deactivate' from the 'Bulk Actions' dropdown menu and then click on the 'Apply' button.

You can now head over to **Tools » Network Setup** page to configure your multisite network.

**Addresses of Sites in your Network**

Please choose whether you would like sites in your WordPress network to use sub-domains or sub-directories. You cannot change this later.

You will need a wildcard DNS record if you are going to use the virtual host (sub-domain) functionality.

☐ Sub-domains like `site1.example.com` and `site2.example.com`

☒ Sub-directories like `example.com/site1` and `example.com/site2`

**Network Details**

**Server Address** The internet address of your network will be `example.com`.

**Network Title**   
What would you like to call your network?

**Network Admin Email**   
Your email address.

[Install](#)

**Tools**

- Available Tools
- Import
- Export
- Network Setup**

On the network setup screen, you will see a notice that you need Apache's `mod_rewrite` module installed on your server. This module is installed and enabled on all the [best WordPress hosting providers](#).

The next thing you need to do is to tell WordPress what kind of domain structure you will be using for sites in your network, e.g. Subdomains or Sub-directories.

After that, you would need to provide a title for your network and make sure that the email address in the Network admin email is correct.

Click on the install button to continue.

WordPress will now show you some code that you need to add to your `wp-config.php` and `.htaccess` file respectively.

1. Add the following to your `wp-config.php` file in `/home/username/example/` above the line reading `/* Tha`

```
define('MULTISITE', true);
define('SUBDOMAIN_INSTALL', true);
define('DOMAIN_CURRENT_SITE', 'example.com');
define('PATH_CURRENT_SITE', '/');
define('SITE_ID_CURRENT_SITE', 1);
define('BLOG_ID_CURRENT_SITE', 1);
```

2. Add the following to your `.htaccess` file in `/home/username/example/`, replacing other WordPress rules:

```
RewriteEngine On
RewriteBase /
RewriteRule ^index\.php$ - [L]

# add a trailing slash to /wp-admin
RewriteRule ^wp-admin$ wp-admin/ [R=301,L]

RewriteCond %{REQUEST_FILENAME} -f [OR]
RewriteCond %{REQUEST_FILENAME} -d
RewriteRule ^ - [L]
RewriteRule ^(wp-(content|admin|includes).*) $1 [L]
RewriteRule ^(.*\.\php)$ $1 [L]
RewriteRule . index.php [L]
```

Once you complete these steps, your network is enabled and configured. You will have to log in again. [Log In](#)

You can use an FTP client or file manager in the cPanel to copy and paste the code in these two files.

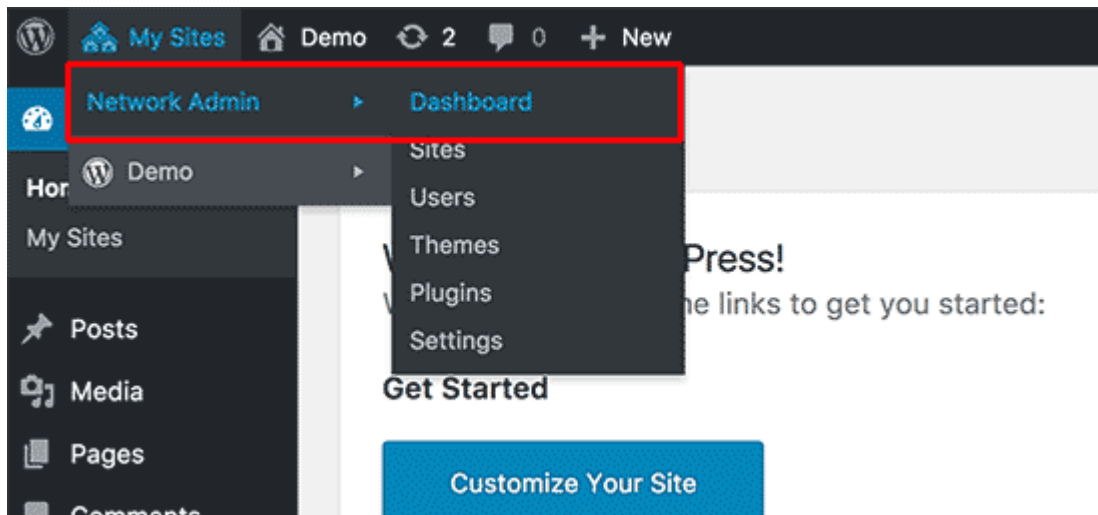

After that you will need to re-login to your WordPress site to access the multisite network.

## Configuring Network Settings

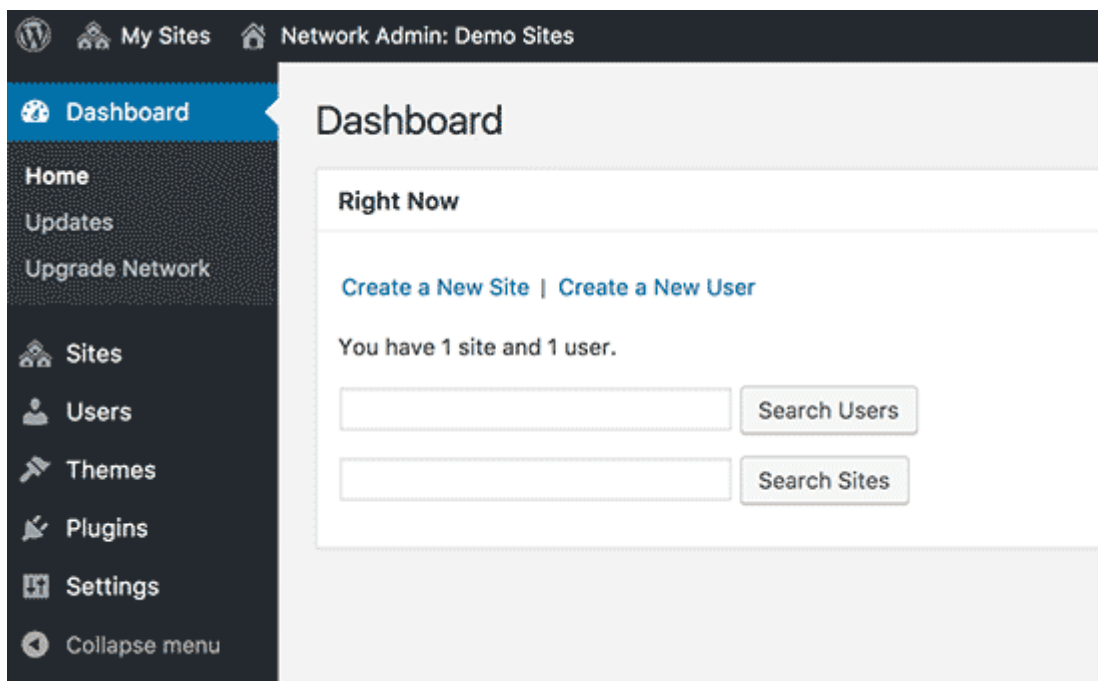

Now that you have setup the multisite network, it is time to configure network settings.

You need to switch to the 'Network Dashboard' to change network settings, add new sites, and configure other settings.

When you take your mouse over to the 'My Sites' menu in the admin toolbar, a flydown popup will appear. Click on the **Network Admin » Dashboard**.

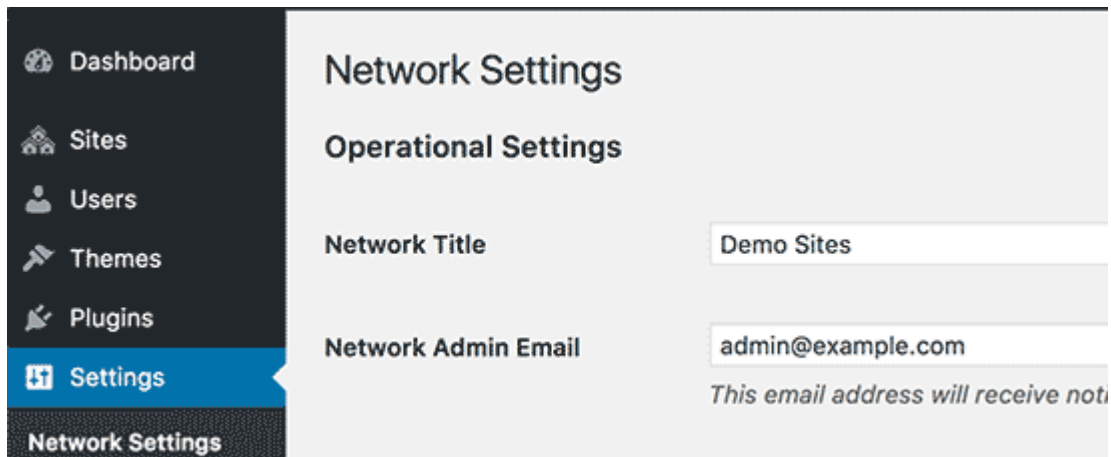

This will take you to the multisite network dashboard. You will notice that there are new menu items to manage your multisite network. You will also see a “Right Now” dashboard widget that allows you to create a new site and add new users.

To configure network settings, you need to click on the ‘Settings’ link in the admin sidebar.

The first option on network settings page is to set your site title and admin email address. These fields will be filled automatically with the network title and admin email you entered during setup.

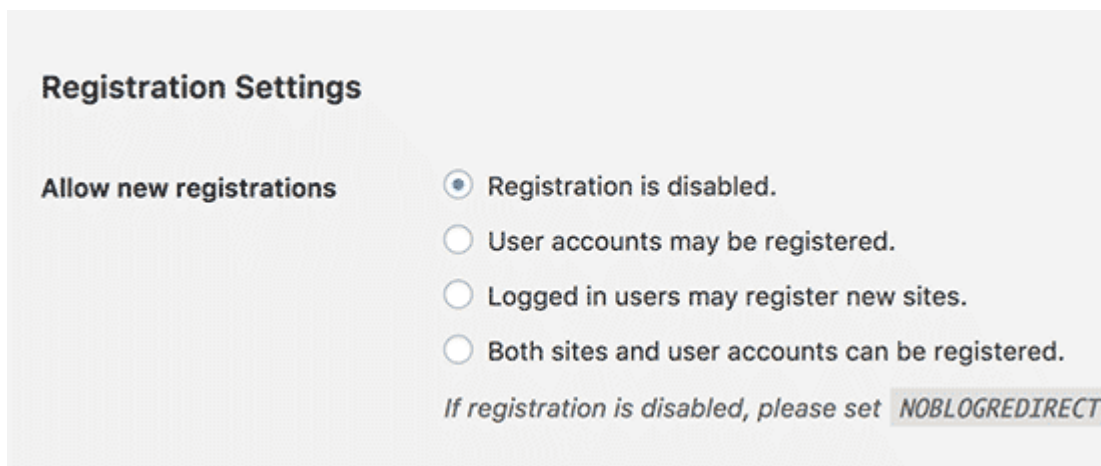

## Opening Your Multisite Network for Registrations

The ‘Registration Settings’ section on the network settings page is probably the most important setting in your network setup.

By default, both user and site registrations are disabled on the network.

You can choose to open your site for user registration, or allow existing users to create new sites, or allow both user and site registration.

If you are opening your multisite network to registration, then you can check the box next to ‘Registration Notification’ option to receive email notifications every time a new user or site is registered.

If you want to allow individual site administrators to add new users on their sites, then you can check the box next to ‘Add New Users’ option.

The screenshot shows a 'New Site Settings' form with the following sections:

- Add New Users:** A checkbox labeled 'Allow site administrators to add new users to their site via the'.
- Banned Names:** A text input field containing 'www web root admin main invite administrator files'. Below it, a note reads: 'Users are not allowed to register these sites. Separate names by'.
- Limited Email Registrations:** A large empty text area. Below it, a note reads: 'If you want to limit site registrations to certain domains. One dorr'.
- Banned Email Domains:** An empty text input field.

Limited Email Registration option allows you to limit site or user registration to email addresses from specific domains. This is particularly useful if you only want to allow people from your own organization to register and create users or sites.

Similarly, you can also ban certain domains from registration.

## New Site Settings

The 'New Site Settings' section allows you to configure default options for new sites created on your multisite network.

You can modify the welcome emails and the contents of first default post, page, and comment in these settings.

| New Site Settings  |  |
|--------------------|--|
| Welcome Email      | <p>Howdy USERNAME,</p> <p>Your new SITE_NAME site has been successfully set up at: BLOG_URL</p> <p><i>The welcome email sent to new site owners.</i></p>           |
| Welcome User Email | <p>Howdy USERNAME,</p> <p>Your new account is set up.</p> <p>You can log in with the following information:</p> <p><i>The welcome email sent to new users.</i></p> |
| First Post         | <p>Welcome to %s. This is your first post. Edit or delete it, then start blogging!</p>   |

As a network administrator, you can change these settings anytime.

## Upload Settings for Your Multisite Network

It is important for you to keep an eye on the usage of your server resources. Under the Upload Settings section, you can limit the total amount of space a site can use for uploads.

The default value is 100 MB which is probably good for at least 100 photo uploads. You can increase or decrease this space depending on how much disk space you have.

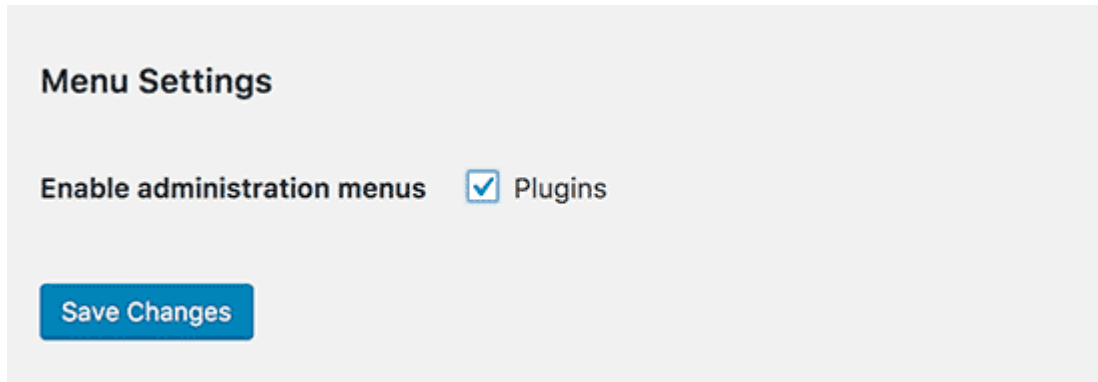

| Upload Settings      |   |
|----------------------|---|
| Site upload space    | <input checked="" type="checkbox"/> Limit total size of files uploaded to <input type="text" value="100"/> MB   |
| Upload file types    | <input type="text" value="jpg jpeg png gif mov avi mpg 3gp 3g2 midi mid pdf doc ppt oc"/> <p><i>Allowed file types. Separate types by spaces.</i></p> |
| Max upload file size | <input type="text" value="1500"/> KB  |

The default upload file types are images, audio, video, and pdf files. You can add [additional file types](#) if you want like doc, docx, odt, etc.

After that, you can choose a file size limit, so that users can't upload insanely large files to the server.

## Plugin Menu Settings

Next, you can jump to the menu settings. It will allow you to enable the administrative menu for the plugins section on your network sites.

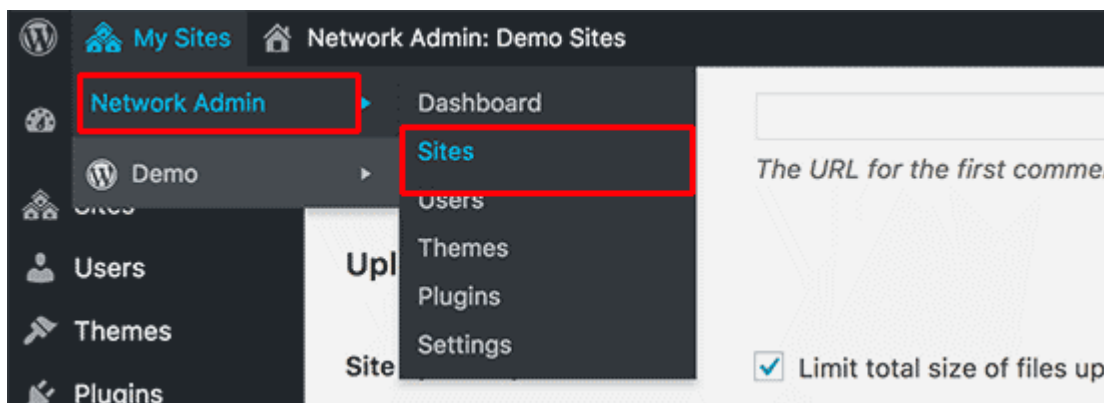

Enabling this will show plugins menu to respective site admins. They can activate or deactivate a plugin on their individual sites, but they cannot install new plugins.

Once you are satisfied with all the configuration settings, make sure to click on the ‘Save Changes’ button.

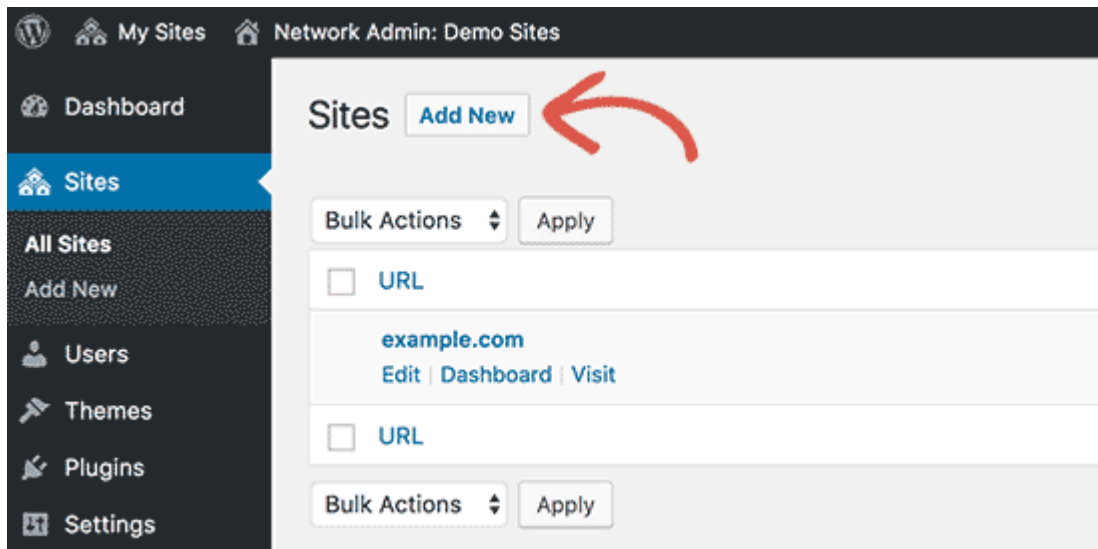

## Adding New Sites to Your WordPress Multisite Network

To add a new site to your WordPress multisite network, simply click on ‘Sites’ under **My Sites » Network Admin** menu in the admin toolbar.

This will show you a list of sites on your current multisite installation. By default, you have your primary site listed as the only site in your WordPress multisite network.

To add a new site, click on the ‘Add New’ button at the top.

On the 'Add New Site' page, you need to provide the site's address. You don't need to type the full address, just the part you want to use as subdomain or sub-directory.

Next, you need to add a site title, and enter the site admin's email address.

You can add an admin email address other than the one that you are currently using to manage your multisite network.

If the email address is not currently in use by another user, then WordPress will create a new user and send the username and password to the email address you enter.

Once you are done, click on the 'Add Site' button.

A new site will be added to your WordPress multisite network. As the network admin, you will receive a new site registration email as well.

If you created a new user, then that user will receive an email with instructions to set a new password and login.

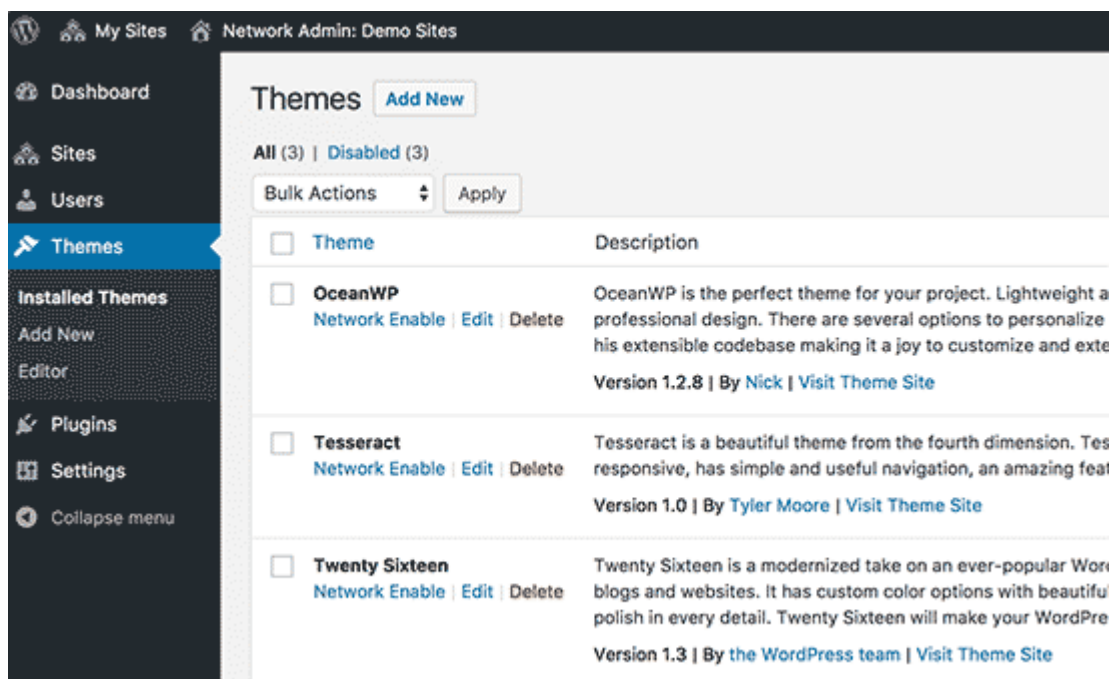

## Adding Themes and Plugins to Your Multisite Network

By default, individual site administrators in a multisite network cannot install themes and plugins on their own.

As the network admin, you can install the respective plugins and themes, so it's available for all sites on your network.

### Installing themes for your multisite network

To add themes, go to **My Sites » Network Admin » Themes** page.

On this page, you will see a list of currently installed themes on your WordPress multisite.

You can make a theme available to other sites by clicking on 'Network Enable' option under that theme. You can also disable a theme by clicking on 'Network Disable' link under the theme. Note: Network Disable option will only appear when the theme is enabled.

To add a new theme, you need to click on the 'Add New' button at the top of your screen and then [install a WordPress theme](#) as you would normally do.

Once the new theme is installed, you will be able to make it available to other sites on your network with the ‘Network Enable’ option.

If you need recommendations on which themes to make available to your network, take a look at our picks of the best WordPress themes that you can use.

- [Best free WordPress blog themes](#)
- [Best free WordPress photography themes](#)
- [Best WordPress multi-purpose themes](#)

## Setting a default theme for your Multisite Network

After you have added a couple of themes, WordPress will still activate the default WordPress theme for each new site.

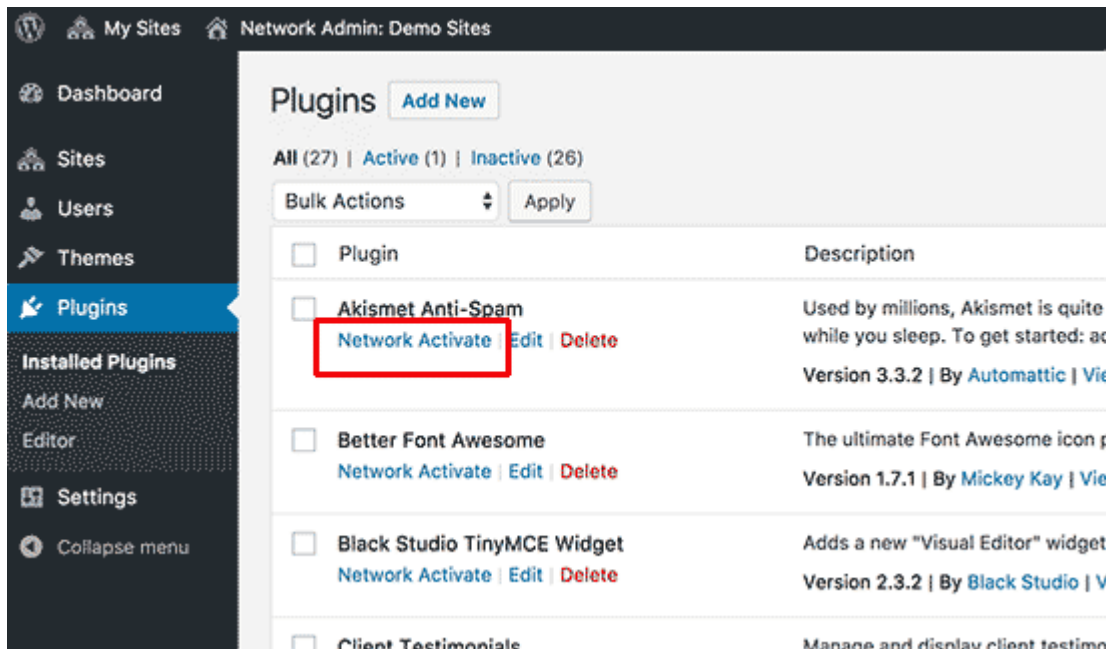

If you want to make another theme to be the default theme for new sites, then you need to add the following code to your wp-config.php file.

```
1// Setting default theme for new sites
2define( 'WP_DEFAULT_THEME', 'your-theme' );
```

Replace your-theme with the name of your theme. You will need to use the name of the theme’s folder, which you can find out by looking at the /wp-content/themes/ folder.

## Installing plugins for your multisite network

Similarly, you can visit **My Sites » Network Admin » Plugins** page to [install plugins](#) and click on the ‘Network Activate’ link below each plugin to activate them on your multisite network.

Following are a few essential WordPress plugins that we recommend for every website:

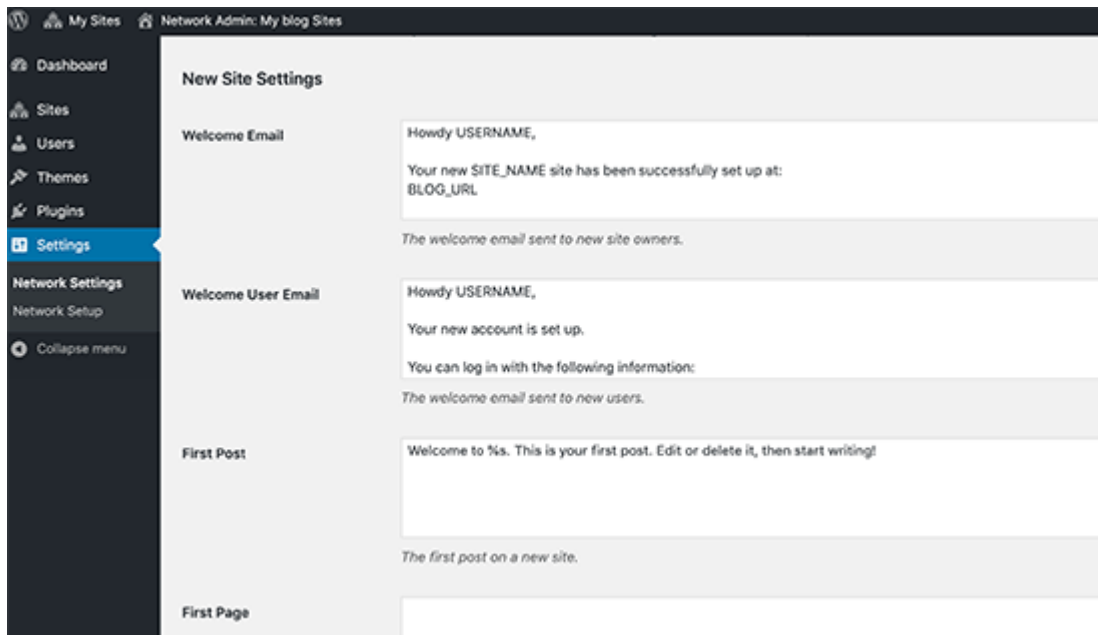

- [WPForms](#) – It is the [best WordPress contact form plugin](#) and allows you to quickly create beautiful forms using simple drag and drop form builder.
- [Yoast SEO](#) – It is the most comprehensive [WordPress SEO plugin](#) on the market and will help you get more visitors from search engines.
- [SeedProd](#) – Site admins may want to see a coming soon page as they work on their sites. SeedProd allows them to add beautiful [coming soon and maintenance mode landing pages](#)
- [WP Mail SMTP](#) – WP Mail SMTP helps you [fix WordPress not sending email issue](#) by using SMTP server to send crucial multisite registration and notification emails.

For more plugin recommendations, see our list of the [essential WordPress plugins](#) for all websites.

**Note:** If you have enabled the Plugins Menu option for site admins in the ‘Network Settings’ previously, then the site administrators can activate or deactivate installed plugins on their own. Site admins cannot delete or install a new plugin on their own.

## Adding Default Content to Multisite Sites

By default, WordPress allows you to edit some default content for each site on your multisite network. You can go to **Settings » Network Settings** page and add them under the section ‘New site settings’.

You can edit the content for the default post, page, and comment. We recommend replacing the default content with something more useful for your site admins.

What if you wanted additional default content to be added to each new site?

By default, WordPress does not give you an option to create additional default content for new sites. If you want to do that, then you will need to [add custom code to your WordPress multisite](#).

In this example, we are going to add a new default page to be created for each new site.

```

1 add_action('wpmu_new_blog', 'wpb_create_my_pages', 10, 2);
2
3 function wpb_create_my_pages($blog_id, $user_id){
4     switch_to_blog($blog_id);
5
6     // create a new page
7     $page_id = wp_insert_post(array(
8         'post_title'      => 'About',
9         'post_name'       => 'about',
10        'post_content'    => 'This is an about page. You can use it to
11        introduce yourself to your readers or you can simply delete it.',
12        'post_status'     => 'publish',
13        'post_author'     => $user_id, // or "1" (super-admin?)
14        'post_type'       => 'page',
15        'menu_order'      => 1,
16        'comment_status'  => 'closed',
17        'ping_status'     => 'closed',
18    ));
19

```

```
20restore_current_blog();
}
```

You can use the same code with little modifications to create default posts for new sites. Check out the following code:

```
add_action('wpmu_new_blog', 'wpb_create_my_pages', 10, 2);
1
2function wpb_create_my_pages($blog_id, $user_id){
3    switch_to_blog($blog_id);
4
5    // create a new page
6    $page_id = wp_insert_post(array(
7        'post_title'      => 'A sample blog post',
8        'post_name'       => 'sample-blog-post',
9        'post_content'    => 'This is just another sample blog post. Feel
10    free to delete it.',
11        'post_status'     => 'publish',
12        'post_author'     => $user_id, // or "1" (super-admin?)
13        'post_type'       => 'post',
14    ));
15
16restore_current_blog();
17}
```

## Troubleshooting WordPress Multisite Issues

Most common issues with WordPress multisite network setup occur due to incorrect configuration of wildcard subdomains and domain mapping issues. Make sure that your web host supports wildcard subdomains before setting up multisite.

Following are some other common issues and their quick fixes.

### Fixing login issues on multisite installs

Another common issue is that when using WordPress multisite with sub-directories, some users are unable to login to the admin area of their sites after they add the required code in wp-config.php file.

To fix this, try replacing

```
1 define('SUBDOMAIN_INSTALL', false);
```

line in wp-config.php file with

```
1 define('SUBDOMAIN_INSTALL', 'false');
```

## Find unconfirmed users

Another issue that you may come across is not being able to find users who registered on your network but didn't get the activation email. To fix this issue, see our guide on [how to find pending unconfirmed users in WordPress](#).

## Exporting a site from multisite to its own WordPress install

Later at some point, you or another site owner may want to export a site from multisite to its own WordPress install. This can be easily done. For step by step instructions see our guide on [how to move a site from WordPress multisite to single install](#).

You may also want to bookmark our ultimate guide of [common WordPress errors](#) and how to fix them. It will save you a lot of time by quickly fixing the most common WordPress issues.

## FAQs About WordPress Multisite Network

Many of our users have asked us plenty of questions about WordPress multisite network and how to use it more efficiently. Following are the most frequently asked questions that we have answered.

### 1. Would I be able to better manage my sites with a multisite network?

To be honest, the answer really depends on your usage scenario.

For example, if your websites are not related to each other, then you would be better off with a multiple site management tool, like [InifiteWP](#).

If you manage multiple sites for a restaurant chain, university, or online magazine, then WordPress multisite will be more efficient.

### 2. Does WordPress multisite make my websites load faster?

Once again it depends on several factors. Better WordPress hosting with plenty of server resources will allow multisite to be faster but then again with these resources, individual WordPress sites will also run faster.

However, on a shared hosting account, traffic spikes will increase memory usage and slow down all websites on the multisite network at the same time. To improve multisite speed, see our guide on [WordPress performance and speed optimization](#).

### 3. Can I add an online store to a WordPress Multisite Website?

Yes, you can [add an online store](#) in WordPress multisite network. Most likely, you will be using an eCommerce plugin like WooCommerce for that, which is compatible with WordPress multisite.

#### **4. Can I install 'x plugin' on my WordPress multisite?**

Some WordPress plugins may not be compatible with WordPress multisite. Normally, plugin authors mention it on the plugin's website and you can avoid installing a plugin that may not work on a multisite setup. However, if it is not mentioned, then it is safe to assume that it is multisite compatible.

#### **4. How do I share user logins and roles across the multisite network?**

By default, a user who is registered on one site cannot register or be added to another site on the same network. That's because they are already registered in the shared WordPress database. However, they don't have any [user role privileges](#) on other sites.

You can use third-party plugins like [WP Multisite User Sync](#) to sync users across the network. However, you need to be careful as you may end up giving someone admin privileges to a site.
